Download FREE Computer Science Notes at TutorialsDuniya.com JATRODUCTION TO PYTHON: * Python is a high-level, interpreted, interactive and object - Oriented Scripting language. 5 27 ۲ Python is High-Level: Rograming Longuage Python is designed to be highly readable. It Uses English Keywords frequently where as other languages use punctuation and it has fewer syntactical Constructions than other languages. Python is Interpreted: Python is processed at suntime by the inter-Pretex. You don't need to compile your program befoxe executing it. Python is Interactive: . You can actually sit at a Rython prompt and interact with the interpreter directly to write your programs. Python is Object-Osiented: Python supports Object - Oriented style or technique of programming that encapsulates code within objects.

Download FREE Computer Science Notes at TutorialsDuniya.com 2 HISTORY OF PYTHON: 0> was developed by Guido Van Rossum * Python in the late 1980's and early 1990's at the National Research Institute for Mathematics and Computer Science in the Netherlands. * Python is desired from many other languages including ABC, Modula-3, C, C++, Algol-68, Smallialk, Unix and other scripting languages. Shell ~ NEED OF PYTHON PROGRAMMING: 1. Software Quality: * Python folys on seadability, coherence and software Quality in general sets it apast from other tools in the scripting world. * Python has deep suppost for more advanced software Veyse mechanisms, such as object-oriented programming (oop).

- 2. Developes Psoductivity * Python code is typically one-third to one-fifth the size of earnivalent C++ or Java Code. that means there is less to type, less to debug and less to maintain * Python program also run immediately, without the lengthy Compile and link steps rearised by some other tools, further boosting programmer speed.
- 3. Support Libraries:
 - * Python Comes with a large Collection of prebuilt and postable functionality, Known as the standard library. This library supports an array of applicationlevel programming tasks, from text pattern matching to network scripting.
 - * Python can be extended with both homegrown libraries and a vast collection of third-party application support software. Python's third-party domain offers tools for website construction, numeric programming, serial post access, game development and much more.

4. Easy to Undexstand:
* Being a Very high-level language, Bython reads like English, which takes a lot of Syntax-learning strongs off Coding beginness.
* Python handles a lot of Complexity for you, so it is Very beginnes - friendly in that it allows beginness to focus on learning Pregramming Concepts and not have to Worry about too much details.

5. Very Flexible :
* As a dynamically typed language, Python is really flexible. This means there are no hard rules on how to build features and you'll have more flexibility rolving problems using different methods.
* Python is also more forgiving of excors , so you'll still be able to compile and rule program until you hit the problematic part.

Download FREE Computer Science Notes at TutorialsDuniya.com * the following are the applications of Python in a wide sange of axeas: Web Application 8 1. Desktop Applications 2. Database Applications 3. Web Scoaping 4. 5. Web Mapping 6. Data Analysis 7. Interactive Web Visualization 8. Computer vision for image and video processing Object Oriented Programming 9. >> PYTHON IDENTIFIERS : * A python identifier is a name used to identify a variable, function, class, module or other objects. * An identifier starts with a letter A-z or a-z or an underscore (-) followed by zero or more letters, undespecte and digits (oto 9). * The following are naming conventions for Python identifies: i) class names start with an uppercase letter. All other identifiers start with a lowercase letter.

ii) Stasting an identifier with a single leading underscore indicates that the identifier is private.
iii) stasting an identifier with two leading underscores indicating a strongly private identifier.
iv) If the identifier also ends with two trailing underscores the identifier is a language - defined special name.

PYTHON KEYWORDS:

* Keywords are reserved words and you cannot use them as constant or variable or any other identifier names.

* All the python keywords contain lowercase letters only.

0 \leftrightarrow VARIABLES :-53 * Variables are nothing but reserved memory locations to 50 Store values. This means when you create a variable, 6 6 You reserve some space in memory. 6 * Based on the data type of a variable, the inter-1 Preter allocates memory and decides what can be stored in the reserved memory. Assigning Values to Variables: * Python variables do not need explicit declaration to regerve memory space. The declaration happens 6 automatically when you assign a value to a variable (The The equal sign (=) is used to assign values to SP 6 C Variables . C Ca Eg: a = 15# An integer assignment 2 6 = 3.12 # A float Co C C = "RISE"# A String L. C. Eg: a=b=c=2 # Assign Single value to several Ca Co 导: a, b, C = 15, 3.12, "RISE" C g # Assign multiple objects to multiple variables C a g A ad T

9

Here, objects is the values to be printed. The sep separator is used between the values. It defaults into a space character. -> After all values are printed, end is printed. It defaalts into a new line. -> the file is the object where the values are printed and its defaurt value is sys. stdout (screen).

> DATA TYPES * The data stored in memory can be of many types. * Python has various standard data types that are used to define the operations possible on them and the Storage method for each of them. * Python has 5 standard data types: 1. Numbers 2. String 3. List 4. Tuple 5. Dictionary 1. Number: --> Number data types store numeric values. -> Number objects are created when you assign a Value to them. Eg: num1 = 5 name = "RISE" -> You can also delete the reference to a number object by using the del statement. Syntax ; del Var1 [, Var2[, Var3[..., VarN]]]

-> Python supports 4 different numerical types: int (signed integers) long (long integers, they can also be represented ;;) in octal and hexadecimal) ii) float (floating point real values) iv) Complex (Complex numbers) 2. Strings :--> Strings in Python are identified as a contiguous set of characters represented in the quotation marks. Python allows for either pairs of single or double quotes. -> Subsets of strings can be taken using the slice operator ([] and [:]) with indexes starting at O in the beginning of the string and working their way from -1 at the end. -> the plus (+) sign is the string concatenation operator and the asterisk (**) is the repetition operator. Eg: stx = 'Hello RISE' Print sta # Prints Complete string Print str[0] # Printy first character of the string # printy characters from and position to 5th position Print str [2:5]

Download FREE Computer Science Notes at TutorialsDuniya.com # Printy string stasting from 2nd index Print str[2:] Position # prints stoing two times Point sta *2 Print str + "TEST" # Prints concatenated string output : Hello RISE H 110 RISE 110 Hello RISE Hello RISE Hello RISE TEST 3. Lists :-> Lists are the most versatile of Python's compound data types -> A list containg items separated by Commans and enclosed within square brackets ([]). -> Lists are similar to array, one difference between -them is that all the items belonging to a list can be of different data type.

P

OPERATORS:-* Python language supposts the following types of operators: 1. Arithmetic Operators 2. Comparison (Relational) Operators 3. Assignment Operators 4. Logical Operators 5. Bitwise Operators 6. Membership Operators 7. Identity Operators

1. Arithmetic Operators: - Assume a= 10, b= 20

Operator	Description	Example
	Adols values on either side of	atb = 30
	-the operator.	
- Subtraction	Subtracts sight hand operand from left hand operand.	a - b = -10
	left hand opesand.	
* Multiplication	Multiplies values on either side of the operator.	a*b = 200
1 Division	Divident left hand operand by right hand operand.	b/a=2
% Modulas	Divides left hand operand by sight hand operand and seturns semainder.	b%a = 0
** Exponent	Performs exponential Calculation on operators	a** b = 10 to the power 20
11	The division of operands where the result	9/12 = 4 and
Floor Division	the division of operands where the result is the autient in which the digits after the decimal Point are removed.	9.0//2.0=4.0

2. Compasison Operators : These operators compare the values on either sides of them and decide the relation among them. They are also called Relational operators. Jacob Assume a= 10, b= 20

OPESatos	Description	Example
==	If the values of two operands are carual then the condition becomes true.	(a = = b) is not true
!=	If the values of two operands are not carval then the condition becomes true.	(a!= b) 18 toue
<>	If values of two operands are not equal, then condition becomes true	(a <> b) is true
>	If the Value of left operand is greater than the value of right operand. Then Condition belones true.	(a > b) is not true.
2	If the value of left operand is less than the value of sight operand, then Condition becomes true.	(azb) is toue
>=	If the value of left operand is greater than or equal to the value of right operand, then Condition becomes true.	(a>=b) 13 not true
2 :	If the value of left operand is 1988 than or equal to the value of right operand, then condition becomes true	(a<=5) 1,8 toue

Download I	FREE Computer Science Notes at Tut	orialsDuniya.com
	ment Operators: assignment operator is the oper ign a new value to a variable	satos used to
	ime a=10 and $b=20$	
Operator	Description	Example
=	Assigns Values from right side operands to left side operand.	$c = a+b = a_{33} s_{19} n_{3}$ value of $a+b$ into C .
+=	It adds sight operand to the left operand and assign the result to left operand.	a + = b
	It subtracts right operand from the left operand and assign the result to left operand.	a - = b which is eavuiva- lent to a = a - b
* =	It multiplies sight operand with the left operand and assign the sesurt to left operand.	a = b which is equiva- left to
1=	st divides left operand with the sight operand and assign the sesuit to left operand	a = a + b a / = b which is carcivaled to $a = a / b$
% =	It takes modulus using two operands and aggign the seguit to left operand.	a : 1 = b which is equivalent to a = a : 1.b
** =	Performs exponential (Power) Calculation on operators and assign value to the left operand	a ** = b which is caluivalent to a = a ** b
11 =	It performs floor division on operators and assign value to the left operand.	$a \parallel = b$ which is equivalent to $a = a \parallel b$

4. Logical Operators: -> Logical operators are typically used with Boolean values. -> Assume variable a holds True and variable b holds False: Operator Description Example If both the operands are true then (a and b) and Logical AND condition becomes true. is False 08 If any of the two operands are a os b non-zero other condition becomes Logical OR 18 True true. Used to reverse the logical state not not (a and b) Logical NOT of its operand. 18 True 5. Bit wise Operators : -> Bitwise operator works on bits and performs bit-by-bit operation. if a= 60 and b= 13 -> Assume operator Description Example Operator Copies a bit to the regult, 8 1286432 16 8421 Binasy AND a = 0011 1100 if it exists in both operands. 6=0000 1101 abb: 0000 1100 $(a \ge b) = 12$ It copies a bit, if it exists in either a= 0011 1100 Binary OR Operand. 6 = 0000 1101 a;b=0011 1101 (a|b) = 61

utorialsDuniya.com outer Science 1. While Loop Statement: -> A while loop statement in Python programming language seperatedly executes a target statement as long as a given condition is true. Syntax :while expression: statement(3) Flow Diagram :while (expression) True Statement(s) -> Here, statement(s) may be a single statement or a block of statements with uniform indent. The Condition may be any expression, and true is any nonzero value. The loop iterates while the condition is true.

Č,

S

5

-> When the condition becomes false, program control Passes to the line immediately following the loop. Example : n = int (input (" Enter number:")) fact =1 i = 1while (i < = n): fact = fact *; i = i + 1Print ("Factorial of given number is : ", fact) Output : Enter number : 5 Factorial of given number is: 120 2. for Loop Statements: --> The for statement in python has the ability to iterative over the times of any servence, such as a list or a string. Syntax : for iterating-var in servience: statement(3)

-> If a servience contains an expression list, it is evaluated first. Then, the first item in the sequence is assigned to the iterating variable. Next, the Statements block is executed. Each item in the list is assigned to iterating variable, and the statements block is executed until the entire servence is exhausted. Flow Diagrami-Item from if no more item in servience Sequence Next item from sequence Execute Statement(3) Example :alist = [10, 20, 30]for ele in alist: Print (ele)

output :-10 20 30 > the built-in function Vange () is the right function to iterate over a sequence of numbers. Vange () generates an iterator to progress integers Stasting with O upto n-1 Sange () Syntax: -1. Vange (stop) Stop : Alumber of integers to generate, starting from zero 2. Vange ([stast], stop [, step]) stast: stasting number of the servuence stop : Generate numbers up to, but not including this number. step: Difference between each number in the sequence.

Download FREE Computer Science Notes at TutorialsDuniya.com

22

3. Nested Loops -> Python programming language allows the use of one loop inside another loop. Nested for loop Syntax: for iterating-var in servence: for iterating var in seavuence: Statement(8) Statement(8) Nested while loop Syntax: while expression: while expression: statement(s) Statement(8) Example: for i in sange (0,3): for j in range (0,3): Print ((i, j))

G

6

6

5

C

Download FREE Computer Science Notes at TutorialsDuniya.com er l 3 output: -6° (0, 0)0 (0.1)(0,2)B (1, 0)S (1,1)(1, 2)0 (2, 0)LOOP CONTROL STATEMENTS:-0 * The loop Control statements change the execution B 3 from its normal seavence B * Python supposts the following control statements: B 3 1. break Statement 3 2. Continue Statement 3 3. pagg Statement 3 1. break Statement: -> The break statement terminates the loop statement and transfers execution to the statement immediately -3 -3 following the loop. Example: letter in 'Python': for if (letter == 'h'): break -Print ("Current letter: ", letter)

2

e

e

A

3. pass statement: > The pass statement is a null operation; nothing happens when it executes. -> the pass statement is also useful in places where Your code will eventually go, but has not been written Jet. Example : for letter in 'Python': if (letter == 'h'): Pags Print (" This is page block") Print (" Current letter: ", letter) output : Cussent letter: P Cussenti letter: y Cussent letter: t This rig Pass block Cussent letter: h Current letter: 0 Current letter: n

Updating Lists : -> You can update single or multiple elements of lists by giving the slice on the left-hand side of the assignment operator, and you can add to elements in a list with the append () method. Example :list1 = [10, "RISE", 8.5, "CSE"] Print ("list1[1]: ", list1[1]) list1[1] = "RGAN" Print (" list1[1]: ", list1[1]) output : list1[1]: 'RISE' list1[1] : "RGAN" Delete List Elements: -> To remove a list element, you can use either the del statement if you know exactly which element you ase deleting.

P

S

)

)

.

Example:
light =
$$\begin{bmatrix} 10, \\ RISE'', 8.5, \\ CSE'' \end{bmatrix}$$

Print ("Before deleting light elements are: ", light)
del light[2]
Print ("After deleting light elements are: ", light)
Output:
Before deleting light elements are:
 $\begin{bmatrix} 10, \\ RISE'', 8.5, \\ CSE'' \end{bmatrix}$
After deleting light elements are:
 $\begin{bmatrix} 10, \\ RISE'', \\ CSE'' \end{bmatrix}$
Basic Light Operations:
1. len() - Find the length of the light.
Eg: dight = $\begin{bmatrix} 10, 20, 30 \end{bmatrix}$
Print (" Number of elements in light: ", len(alight))
Output:
Number of elements in light: 3

2. + - Concatenation of lists.
Eg:
a list =
$$\begin{bmatrix} 10, 20 \end{bmatrix}$$

b list = $\begin{bmatrix} 30, 40 \end{bmatrix}$
print (alist + blist)
output:
 $\begin{bmatrix} 10, 20, 30, 40 \end{bmatrix}$
3. * - Repetition of list elements
Eg:
alist = $\begin{bmatrix} 10, 20, 30 \end{bmatrix}$
Print (aligt * 2)
Output:
 $\begin{bmatrix} 10, 20, 30, 10, 20, 30 \end{bmatrix}$
4. in - Membership operator which returns True when
element present in list. False otherwise.
Eg:
alist = $\begin{bmatrix} 10, 20, 30, 40 \end{bmatrix}$
Print (20 in aligt)
print (50 in aligt)
Output:
True
False

5

Built-in Functions and Methods : 1. len (): This method setusns the number of elements in the list. Syntax : len (1:st) 2. max () : This method seturns the element from the list with maximum value. Syntax : max (list) min(): This method seturns the element from the 3. list with minimum value. Syntax : min (1:8t) list(): This method takes servuence types and converts them to lists. This is used to convext a given 4. tuple into list. Syntax :

list (sea)

-> TUPLES: * A tuple 18 a searce of immutable Python objects. * Tuples are servences, just like lists. * The main difference between the tuples and the lists is that the tuples cannot be changed unlike lists. Tuples use parentheses, whereas lists use samare brackets. Creating a tuple: tuple1 = (10, "RISE", 8.5, "CSE") tuple2 = ();Like string indices, tuple indices start at 0, and they can be sliced, concatenated and so on. Accessing Values in Tuples: tuple1 = (10, "RISE", 8.5, "CSE") Print ("tuple1[2]: ", tuple1[2]) print ("tuples[1:3]:", tuples [1:3]) output:tuple1[2]: 8.5 tuple1[1:3]: ("RISE", 8.5)

1 th 10 Updating Tuples : -> Tuples are immutable, which means you cannot update 10 NP. or change the values of tuple elements. 10 A. Delete Tuple Elements: No. > Removing individual tuple elements is not possible. 1 and a -> To explicitly remove an entire tuple, just use the B 3 del statement. 3 3 Basic Tuples operations: 3 1. len() - Finds the length of the tuple. 3 Eg:-- S atuple = (10, " RISE", 8.5, "CSE") -J Print (len (tuple)) T output: -10-5 3 4 + - Concatenation -5 2. 5 Eq:atuple = (10,20,30,40) 9 3 btuple = (50, 60, 70) 3 Print (atuple + btuple) 9 output: 5 (10, 20, 30, 40, 50, 60, 70) 2 2 max (tuple) 2

 43 0 3. min() - This method setusys the element from 3 the tuple with minimum value. 20 Syntax : 0 min (tuple) ap OF: 4. tuple() - This method converts a list of items into 03 tuples. 3 Syntax : 0 tuple (sear) 3 3 3C> DICTIONARY: * Dictionary is an unordered set of Key: value pairs, 5 with the revuisement that the keys are unique (within 5 J one dictionary). * Unlike servuences, which are indexed by a range of 2 numbers, dictionaries are indexed by keys, which can 1 be any immutable type; strings and numbers can always be Keys. * Creating Dictionary : adict = { 'vollno': 8 , 'name': "RISE" , 'branch : "CSE" f adict = { } # Empty dictionary

Download FREE Computer Science Notes at TutorialsDuniya.com 12 Accessing Values in Dictionary : adict = { 'Xollno': 8 , 'name': "RISE", 'branch': "CSE" } Print ("adict ['branch']: ", adict ['branch']) output:adict['branch']: 'CSE' Updating Dictionary: * You can update a dictionary by adding a new entry or a key-value pair. Example:adict = { 'vollno': 8 , 'name': "RISE", 'branch': "CSE" } Print (adict) adict ['name'] = "RGAN" adict ['address'] = "Ongole" Print (adict) output : ¿'vollno': 8 , 'name': "RISE" , 'branch': "CSE"} { 'Vollno': 8, 'name': "RGAN", branch': "CSE", 'address': "ongole"} Delete Dictionary Element: * You Can remove individual dictionary elements use del statement.

Example: adict = { 'vollno': 8 , name': "RISE" , branch': "CSE"} Print (adict) del adict ['soilno'] Print (adict) del adict Print (adict) Note: An exception is raised because after del dict, the dictionary does not exist anymore. output: { 'Vollno': 8 , 'name': "RISE" , 'branch': "CSE"} { `name': "RISE", `branch': "CSE"} Essos: adict is not defined Properties of Dictionary Keys: * these are two impostant points to remember about dictionary Keys: i) More than one entry per key is not allowed. This means no duplicate Key is allowed. When duplicate Keys are en countered during assignment, the last assignment is to be Considered. ii) Keys must be immutable. This means you can use strings, numbers of tuples as dictionary keys but something like ['Key'] is not allowed.

12. Values () - This method seturns a list of all values ava-6 ilable in a given dictionary. 6 Syntax : dict. values () 6 SETS :-* A set is an unoxdexed Collection of items. Every 6 element is unique (no duplicates) and must be immu-6 table (which Cannot be changed). Create a set: * A set is created by placing all the items (elements) inside custy braces [], separated by comma or by using the built-in function set (). * It can have any number of items and they may be different types (integer, float, tuple, string etc.). But a set cannot have a mutable element like list or dictionary, as its elements. a, Bet = { 8.5, "RISE", (1,2,3) } (08) aset = set ([8.5, "RISE", (1,2,3)])

C

13. Symmetric-difference() - Return the symmetric diffevence of two sets as a new set. syntax :set1. symmetric _ difference (set2) 14. Symmetric_difference_update () - Update a set with the symmetric difference of itself and another. Syntax : set1. symmetric_difference_update (set2) 15. Union () - Return the union of sets in a new set. Syntax :set1. union (set2) 16. update () - Update a set with the union of itself and other. Syntax : -, set 1. update (list [, set 2]) 17. dig cased () - Remove an element from set if it is a member. Do nothing if the element is not in set. Syntax: set. discard (clement)

SEQUENCE : * In Python, servuence is the generic term for an Ordered set. * These are several types of sequences in python, the following three are the most important: 1. Listy 2. Tuples 3. Strings LIST COMPREHENSIONS: * Python Supposts computed lists called list comprehen-Sions. Syntax : list1 = [expression for variable in sequence] the expression is evaluated once, for every item where, in the sequence. * List comprehensions help programmers to create lists in a a concise way. This is mainly beneficial to make new lists where each element is the obtained by applying some operations to each member of another sequence or iterable.

DEFINING FUNCTIONS: * A function is a block of organized relegable code that is used to perform a single, related action. * Functions provide better modularity for your application and a high degree of code reusing. * Python gives you many built-in functions like input(), Print () etc., but you can also create your own functions. These functions are called user-defined functions. * Here are simple rules to define a function in Python: i) Function blocks begin with the keyword def followed by the function name and pasentheses(()). ii) Any input pasameters or asguments should be placed within these poventheses. iii) The first statement of a function can be an optional statement - the documentation string of the function or docstring. iv) The code block within every function starts with a colon(:) and is indented. V) The statement seturn [expression] exits a function, optionally passing back an expression to the caller.

6

60

Co

Co

6

3

Correga.

20 years

0

A setusn statement with no asguments is the same as return None. Syntax : def function_name (pasameters): "function_docstring" function_suite return [expression] -> CALLING A FUNCTION: * Once the basic structure of a function is finalized, you can execute it by calling it from another function or directly from the Python prompt. Example: def display (sto1): "This displays a passed string into this function" Print (str1) seturn display (" Hello Woold ") output :. Hello World

> PASS BY REFERENCE VS VALUE * All parameters in the Python language are passed by référence. It means if you change what a parameter refers to within a function, the change also reflects back in the Calling function. Example: -# Pass By Reference def changelist (alist): "This changes a passed list into this function" Print ("List elements inside the function before change : ", alist) Print ("List elements inside the function after alist [2] = 25 change: ", alist) seturn alist = [10, 20, 30, 40, 50] Print ("Before Calling function, list elements are:", alist) changelist (alist) Print ("After Calling function, list elements are: ", alist)

-> Keywood asguments are related to the function Calls. When you use keyword asymmetry in a function Call, the Caller identifies the arguments by the parameter name. > This allows you to skip asguments or place them out of order because the python interpreter is able to use the Keywords provided to match the values with parameters. -> A default asgument is an asgument that assumes a 3. Defauit Asguments : defauit value if a value is not provided in the function Call for that asgument. 4. Variable - length Arguments: > You may need to process a function for more asguments than you specified while defining the function. These asguments are Called Variable-length asguments and are not named in the function definition. Unlike required and defauit arguments.

Syntax :def functionname ([formal-args,] * Var-args-tuple): "function. doc string" "function-suite return [expression]

-> An asterisk (*) is placed before the variable name -that holds the values of an non-keyword variable asguments. This tuple remains empty if no additional asguments are specified during the function Call. ANONYMOUS FUNCTIONS : * Anonymous functions are not declared in the standard manner by using the def Keyword. You Can use the lambda keyword to create small anonymous functions. * Lambda forms can take any number of asguments but return just one value in the form of an expression. They cannot contain commands or multiple expressions . * An anonymous function cannot be a direct can to Print because lambda revuires an expression. Lambda functions have their own local namespace and *cannot access variables other than those in their Parameter list and those in the global namespace. Syntax :lambda [arg1 [, arg2, argn]]: expression

8 Example : 0 add = lambda asg1, asg2: asg1 + asg2 G 5 Print (" Addition of two numbers is : ", add (10,20)) C C Print ("Addition of two numbers is: ", add (9,7)) C Output : Addition of two numbers is : 30 Addition of two numbers is : 16 FUNCTION RETURNING VALUES (Fruitful Function): ∽≫ * The statement return [expression] exits a function, optionally passing back an expression to the caller. -A seturn statement with no arguments is the same as and the 6 return None. Example : 6 2 def add (x,y): $z = \chi + y$ seturn z Cona = int (input ("Enter a value:")) b = int (input ("Enter b value: ")) C = add(a,b)print ("Sum of two numbers is : ", c)

()

Download FREE Computer Science Notes at TutorialsDuniya.com output :. Enter a Value: 9 Enter 6 Value: 7 Sum of two numbers is : 16 > Scope OF VARIABLES: * An variables in a program may not be accessible at all locations in that program. This depends on Where you have declared a variable. * The scope of a variable determines the postion of the Program where you can access a pasticular identifier. These are two basic scopes of variables in python -1. Giobal Vasiables The variables that are defined outside a function body have a global scope. This means that global variables can be accessed throughout the program body by all functions. 2. Local Variables the variables that are defined inside a function body have a local scope. This means that local variables can be accessed only inside the function in which they are declared.

Example : # This is global variable a = 5 def display (): # Here a is local variable a = a + 3Print (" Inside the function, value of a is:", a) seturn display () Point ("outgide the function, value of a is: ", a) output : Inside the function, value of a 18:8 Outside the function, value of a 18:5 MODULE * A module is a file consisting of Python code. A module can define functions, classes and variables. A module can also include sunnable code. impost Statement :--> You can use any python source file as a module by executing an impost statement in some other Python source file.

Syntax : impost module 1 [, module 2 [, ... moduler]] When the interpreter encounters an impost statement, it imposts the module if the module is present in the seasch path. Example: - Creating module welcome.py # Creating a module def greet (name): Print (" Wel Come ", name) setusn T Program input_module.py that imports welcome.py # Impost module welcome 5 import welcome -9 name = input ("Enter your name:") 5 5 Welcome.greet (name) -) -) output -7 Enter your name: RISE Welcome RISE 9

* In the example, modules and modules are imposted into the same program. Each module has a function display (), which produces different resourts. When we call the display() from the main module, these will be a name clash as it will be difficult to determine which of these two functions should be called. Namespaces provide a means for resol-Ving such problems.

* In Python, each module has its ownspace. This namespace includes the names of all items (functions and variables) defined in the module. Therefore, two instances of display (), each defined in their own module, are distinguished by being funy availified with the name of the module in which each is defined as module 1. display and module 2. display. This is illustrated as follows:

impost module 1 impost module 2 name = input ("Enter your name:") module 1. display (name) # sefess to display in module1 module 2. display (name) # refers to display in module 2

ふれれる

#Built-in Namespace

60 b Local, Giobal and Built-in Namespaces: B * Jusing a program's execution, there are three main USP namespaces : B i) Local namespace - the local namespace has identi-E E fiers defined in the cussently executing function. 0 F ii) Giobal namespace - The global namespace contains E identifiers of the cussently executing module. and D the 1 D iii) Built-in namespace - The built-in namespace Contains D D names of all the built-in functions, constants, etc. D that are already defined in python. D D Example: D # Global namespace def largest (numbers): large = 0 # local namespace for i in numbers: if (i > large): large = 1 Seturn large numbers = [5, 4, 9, 3, 2]Print ("Largest number 18: ", largest (numbers)) print ("Sum of these numbers: ", "sum (numbers))

output: -Largest number is : 9 Sum of these numbers: 23 -> PACKAGES IN PYTHON * A package is a hierarchical file directory structuse that has modules and other packages within it. Like modules, you can very easily create packages in Python. * Every package in python is a directory which must may not even have a single line of code. It is Simply added to indicate that this disectory is not an Ordinary directory and contains a Python package. In your programs, you can import a package in the Same way as you impost any module. Syntax: impost MyPackage. MyModule

from MyPackage impost MyModule

* The --init_-. Py is a very impostant file that also determiness which modules the package exposts as the API, While keeping other modules internal, by oversiding the -- all -- Variable as shown below:

 $-_in;t_-.Py$ $-_all_= ["MyModule"]$

Key Points to Remember: i) Packages are searched for in the path specified by sys. path.

ii) --init--.py file can be an empty file and may also be used to execute initialization code for the Package or set the -- all -- Variable.
iii) the import statement first checks if the item is defined in the package. If it is unable to find it, an ImportEssor exception is raised.

iv) When imposting an item using syntax like impost item. subitem. subitem, each item except the last must be a package. That is, the last item should either be a module or a package. In no case it can be a class or function or variable defined in the previous item.

V) Packages have an attribute -- path -- which is initialized with a list having the name of the directory holding the _init _ . . Py file. The _ path _ attribute can be modified to change the future scarches for modules and Sub-packager contained in the package.

20 100 CLASSES AND OBJECTS : () * Classes and objects are the two main aspects of F 13 Object oriented programming. In fact, a class is the E basic building block in Python. De 2 * A class creates a new type and object is an De instance of the class. P C * Classes provides a blueprint or a template using which P objects are created. In fact, in Python everything is an R CF. object or an instance of some class. 3 Defining Classes : 3 J class class-name: J < statement -1> 3 < statement-2> 3 3 < statement - N>) 9 * Class definition starts with a Keyword class followed by) the class-name and a colon (:). The statement in the definition can be any of these - seavuential instructions, 9 decision control statements, loop statements and can even 9 include function definitions. 9 ۲

Com.

* Vasiables defined in a class are called class variables and functions defined inside a class are Called class methods. Class variables and class methods are together known as class members. The class members can be accessed through class objects. Creating Objects : * Once a class is defined, the next job is to create an object or instance of that class. The object Can then access class variables and class * methods using the dot operator(.). Syntax : object_name = class_name () * the syntax for accessing a class member through the class Object is object_name. class_member_name Example: Class A: Vollno = 501

Print (" Roll Number 18", Aobj. vollno)

Aobj = A()

3

output : Roll Number is 501 7. 1 - 5 - 5 - 1 C -> CLASS METHOD AND SELF ARGUMENT: * Class methods are exactly same as ordinary functions that we have been defining so fax with just one 8 mail difference. Class methods must have the first asgument named as self. This is the first asgument -that is added to the beginning of the pasameter list. * The self argument refers to the object itself. That is, the object that has called the method. This means -that even if a method that takes no asguments, it Should be defined to accept the self. Example : class Addition: a=10 b = 20def result (self): C= self. a + self. b Print ("Sum of two numbers is", c) obj = Addition () Print ("Numbers are : ", obj.a, obj.b) obj. result ()

4. Multi-path Inheritance: * Deviving a class from other devived classes that are in turn derived from the same base class is called multi-path inheritance.

> PolyMORPHISM AND METHOD OVERRIDING: * Polymosphism refers to having several different forms. It is one of the Key features of OOP.

- * Polymorphism enables the programmess to assign a different meaning or usage to a Variable, function or an object in different contexts.
- * In Python, method oversiding is one way of implementing Polymorphism.
- * Method overriding is the ability of a class to change the implementation of a method provided by one of its ancestors.

Example: Class BaseCiass 1 (Object): def __init__(self): Print ("Base Class 1") class Base Giass 2 (object): def __init_-(self): Print (" Base Class 2") Class Desived Class (Base Ciass 1, Base Ciass 2): Pass ObjDC = Derived Class () autput :-Base Class 1 * In the above method, an object of desived class is made. Since these is no __init__() method in the desived class, the __ init_ C) method of the first base class gets executed. * A super() Call can be made inside any method. This means that all methods can be modified via oversiding and calls to super. The call to super can also be made at any point in the method; we don't have to make the call as the line in the method.

Example: -Class A: -- Value = 5 def display (self): Print ("In class value is: ", self. -- value) $ob_j A = A()$ ObjA . display () Print (" value is: ", objA. -- Value) * The above code shows error when it is executed because name attributes with a double undergoose Prefix will not be directly visible to outsiders. * You Can access such attributes as object. _ className _ attalame. Example: -Class A: - value = 5 def display (self): Print ("In class value is:", seif. __ value) objA = AC) objA. display () Print (" Value is : ", objA. _ A __ Value) output:-In class value is: 5 value is: 5

12 ERROR AND EXCEPTION: 0 * The programs that we write may behave abnormally or unexpectedly because of some essons and/or expections. * The two common types of essors that we very often encounter are syntax errors and logic errors. * Logic essors occurs due to poor understanding of problem and its solution, Syntax essors arises due to poor understanding of the language. * Exceptions are run-time anomalies or unusual conditions (such as divide by zero, accessing asrays out of its bounds etc.,) that a program may encounter during * Like essass, exceptions can also be categosized as Synchronous or asynchronous exceptions. * Synchronous exceptions (like divide by zero, asray index out of bound etc.,) Can be controlled by the program. Asynchronous exceptions (like an intersupt from the keyboard) hasdware malfunction or disk failure) are caused by events that are beyond the control of the program.

Example:a=5 6=0 c= a/b Print (" Result 18: ", c) * In the above program, at line 3 we get an exceie., ZesaDivisionError: integer division or modulo by zero > HANDLING EXCEPTIONS: * We can handle exceptions in our program by using try block and except block. A Critical operation which Can vaise exception is placed inside the try block and the code that handles exception is written in except block. Syntax :toy: statements except Exceptional ame: Statements * The try statement works as follows: Step 1: Fixst, the try block is executed.

Step 2a: If no exception occuss, the except block is skipped.

step 26: If an exception occuss, dusing execution of any statement in the try block, then,

i) Rest of the statements in the try block are skipped.

- ii) If the exception type matches the exception named after the except keyword, the except block is executed and then execution Continues after the try statement.
- iii) If an exception occurs which does not match the exception named in the except block, then it is passed on to outer try block (in case of nested try blocks). If no exception handler is found in the program, then it is an unhandled exception and the program is texminated with an error message.

Example: num = int (input (" Enter numerator:")) deno = int (input ("Enter denominator:")) toy : a/uo = num/deno print (" Quotient : ", avuo) except ZeroDivision Error: Print ("Denominator Cannot be zero.")

Download FREE Computer Science Notes at TutorialsDuniya.com output : Enter numerator: 5 Enter denominator: 0 Denominatos Cannot be zeso RAISING EXCEPTIONS: * You can slowly raise an exception using raise keyword. Syntax :-Vaise [Exception [, args [, trackback]]] Here, Exception is the name of exception to be raised. asgs is optional and specifies a value for the exception asgument. If asgs is not specified, then the exception asgument is None. The final asgument, trackback is also optional and if present, is the trackback object is used for the exception. Example 1: toy : num = 10Print (num) Value Error Print ("Exception occurred ... Program Terminating ... ") except: output : Exception occursed ... Program Terminating ...

Example 2 :a = int (input ("Enter numerator value:")) b = int (input ("Enter denominator value:")) try : if (b==0): raise Exception (b) C= alb Print (" C= ", C) except Exception as e: Print (" Denominator can not be ", e) output: Enter numerator value: 5 Enter denominator value:0 Denominator Can not be O USER - DEFINED EXCEPTION :-* Programmers may name their own exceptions by creating a new exception class. Exceptions need to be derived from the Exception class, either directly or indisectly.

1 1 Example: -1 class MyException (Exception): F def __ init__ (self): 0 Self. msg = "Exception occursed" 0 0 0 try : 2 raise (MyException ()) 0 except MyException as e: D 0 print (c. msg) 0 5 5 5))))) 2 666
